PRESENTING CLINICAL SIGNS

Cat presents BAR and IGC on D/O for exam.
"O" notes blood in vomit and Hx of URD (Mycoplasma recently dx'd).

CBC - low PLT's (confirmed manually), slight increase in Glob's and QPI (4.7).

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The urinary bladder wall is normal in thickness and the mucosal surface is smooth. The bladder is moderately distended. Luminal contents are mostly anechoic. No cystic calculi are observed. The region of the trigone and the proximal urethra, visible to a depth of 4 cm, are normal.

The left kidney is normal in size (4.45 cm in length) with a normal shape, architecture and smooth peripheral margins. There is a normal 1:3 cortex to medulla ratio with mild loss of corticomedullary distinction. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

The right kidney is normal in size (4.36 cm in length) with a normal shape, architecture and smooth peripheral margins. There is a normal 1:3 cortex to medulla ratio with mild loss of corticomedullary distinction. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

Adrenal Glands

The left adrenal gland is normal size (0.24 cm width). Normal shape and glandular echogenicity. The phrenicoabdominal vein and surrounding vasculature are normal.

The right adrenal gland is normal size (0.49 cm width). Normal shape and glandular echogenicity. The phrenicoabdominal vein and surrounding vasculature are normal.

Spleen

The spleen is normal in size (0.77 cm in width at the level of the hilus) with a normal capsular contour. There is appropriate echogenicity and echotexture. No focal lesions are observed. Splenic vasculature is normal.

Liver

The liver is subjectively normal in size with normal curvilinear peripheral contours. The parenchyma is isoechoic relative to the spleen and diffusely homogeneous in appearance. No distinct focal lesions are observed. Vascular and biliary tracts are of normal volume with no evidence of congestion. The portal vein to caudal vena cava ratio is approximately 1:1.

The gall bladder lumen is moderately distended. The wall is thin and smooth. Luminal contents are mostly anechoic. The cystic and common bile ducts are normal.

Gastrointestinal

The stomach and intestine are free of stasis and exhibit normal peristaltic activity. The gastric lumen moderately distended with ingesta consistent with a post-prandial presentation. The gastric wall and pylorus are normal in thickness with a normal layering pattern. The pyloric outflow tract is patent. The small intestinal lumen is segmentally dilated with chyme. The small intestinal wall thickness is normal. There is disruption in the normal 1:3 muscularis: mucosal ratio in most segments. Discreet masses are not identified. The ileocecal colic junction and colonic wall are normal. No obstructive disease is noted.

Pancreas

The left limb of the pancreas is normal in size with normal curvilinear peripheral contours. The parenchyma is largely isoechoic relative to surrounding omental fat and slightly mottled in appearance. The pancreatic duct is visible but not overtly dilated. There is no evidence of peripancreatic inflammation or effusion.

Lymph nodes

A cluster of prominent to enlarged hypoechoic mesenteric lymph nodes are visualized, one of the nodes measuring 2.95 x 0.82 cm.

Free Abdomen

There is no obvious evidence of free fluid.

Other

A brief echocardiogram reveals no obvious evidence of pericardial or pleural effusion in the visible window.

ULTRASONOGRAPHIC FINDINGS

Primary Findings:

- The mesenteric lymphadenopathy could be consistent with emerging neoplasia (i.e., lymphoma), lymphadenitis or lymphoid hyperplasia.
- The small intestinal wall changes could be consistent with inflammatory bowel disease, emerging lymphoma or normal variation for this older feline patient.

Secondary Findings:

- The pancreatic changes are most consistent with age-related parenchymal remodeling, potentially secondary to a prior inflammatory episode, early fibrosis or chronic pancreatitis.
- Bilateral nonspecific, age-related renal changes

*Ultrasound guided fine needle aspiration of a mesenteric lymph node was performed at the end of this study without incident.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

1. Submission of mesenteric lymph nodes aspirates for cytologic evaluation is recommended.
2. Also consider a GI panel including serum cobalamin, folate, TLI and PLI.
3. If the above diagnostics are inconclusive, consider endoscopic or surgical GI biopsies. Three-view thoracic radiographs are recommended prior to anesthesia to assess cardiopulmonary status.
