PRESENTING CLINICAL SIGNS

Screening for possible abdominal mass effect on radiographs. Concern for possible hepatocutaneous syndrome vs cutaneous lymphoma vs other for recurring/chronic skin lesions, weight loss despite good appetite. Radiographs - (Abdomen) Stomach full of ingesta, mix of air and ingesta throughout GI in 'mottled' pattern with some bowel loops appearing caudally displaced. Undefined mass effect appreciated in the right mid to caudal abdomen. Visible thorax demonstrates light stippling throughout, extending to body wall (R/O chronic changes "old dog lung" type fibrosis vs metastasis, etc).

Abnormal PE/Chem/CBC/UA Results: Mild ALT and ALP elevation Anemia

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The urinary bladder is adequately distended with anechoic contents. No masses, inflammatory changes, echogenic sediment or cystoliths are observed. The urinary bladder, trigone and visible pelvic urethra are normal in thickness with a smooth mucosal surface.

Kidneys are overall normal in size and shape with smooth peripheral margination. A normal 1:3 cortex to medulla ratio is maintained. The medulla and cortices are uniform in texture with some mild increased cortical echogenicity and mild loss of corticomedullary distinction, expected in this age patient. There is no evidence of pyelectasia, mineral or infarcts observed. Left kidney measured 5.38 cm. Right kidney measured 5.14 cm.

Adrenal Glands

The right adrenal gland is normal in size (0.80 cm at cranial pole and 0.50 cm at caudal pole), shape and overall architecture, echogenicity and echotexture. Visible surrounding vasculature appears normal.

The left adrenal gland is normal in size (0.60 cm at cranial pole and 0.70 cm at caudal pole), shape and overall architecture, echogenicity and echotexture. Visible surrounding vasculature appears normal.

Spleen

The spleen is subjectively normal in size with a normal smooth capsular contour. Parenchyma is appropriately finely textured and homogenous with normal echogenicity relative to surrounding tissue (hyperechoic to liver). No focal nodules or masses are observed. Splenic vasculature appears normal.

Liver

Liver is subjectively enlarged with mildly irregular margins. Parenchyma is markedly heterogenous characterized by multiple poorly defined hypoechoic nodules within otherwise hyperechoic liver parenchyma. Visible vasculature and biliary tree appear normal without distension or congestion

The gallbladder is non-distended in size. The wall is smooth without visible thickening. Luminal contents are primarily anechoic. There is no evidence of cystic or common bile duct dilation.

Gastrointestinal

The visible stomach wall is normal in thickness and layering. The lumen of the stomach is mildly distended with a small to moderate amount of echogenic non-shadowing luminal contents and gas

consistent with normal ingesta. There is no evidence of obstruction, foreign material or infiltrative disease. Pyloric outflow tract appears patent.

The visible small intestines are normal in wall thickness and layering. Small intestinal motility appears adequate (1-3 contractions per min). The lumen is mildly distended with echogenic non-shadowing luminal contents and gas consistent with normal ingesta/chyme. There is no evidence of obstruction, foreign material or infiltrative disease.

The visible colon is normal in wall thickness (< 0.2 cm) and layering. Contents are consistent with normal formed feces and gas.

Pancreas

The pancreas that is observed appears appropriately isoechoic to surrounding omental fat. Visible capsule is smooth and normal in contour. Visible pancreatic parenchyma is homogenous and unremarkable. There is no visible pancreatic duct dilation. There is no evidence of active peripancreatic inflammation.

Free Abdomen

There is no visible free peritoneal effusion noted in these images.

There is no apparent pathologic lymphadenopathy noted in these images.

PRIMARY FINDINGS

- The markedly heterogeneous liver could represent a benign process such as nodular hyperplasia, steroid or vacuolar hepatopathy, extramedullary hematopoiesis, or other chronic inflammatory disease, or infiltrative neoplasia such as round cell neoplasia or even metastatic neoplasia versus other, which can't be ruled out without tissue sampling.

SECONDARY FINDINGS

- Mild to moderate age related kidney changes.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Three view thoracic radiographs are recommended for further assessment of cardio-pulmonary status as well as to further evaluate for any evidence of metastatic disease, if not recently evaluated.

Fine needle aspirates of the liver are recommended if patient's coagulation status is appropriate.

Given patient's history and the concern for other more potentially more serious cutaneous disease, consultation with a veterinary dermatologist for additional sampling and potentially biopsies of the skin could also be considered.

Other than supportive/symptomatic medical management of clinical signs, further treatment recommendations are largely dependent on results of the above.
