PRESENTING CLINICAL SIGNS

Recently diagnosed cardiac murmur , slowing down, When he goes outside, he gets weak sometimes and sits down. Seems ok otherwise.
Abnormal PE/Chem/CBC/UA Results: Noted grade 3/6 cardiac murmur, Reg/Reg Rate, no noted arrhythmias. Blood work pending

ULTRASONOGRAPHIC EXAMINATION OF THE HEART

The echocardiogram in this patient demonstrated normal **left atrial** size based on 3 different LA measurement methods. Chamber volumes and echogenicity were normal. The cranial and caudal **mitral** valve leaflets presented vegetative thickening consistent with endocardiosis. Doppler indicated measurable insufficiency. The **left ventricle** presented thicknesses with linear contour and was not dilated nor restricted. The **myocardium** presented normal echogenicity without subjective evidence of significant fibrotic or ischemic disease. **Contractility** of the ventricular walls was adequate and in normal range for this patient evidenced by the fractional shortening measurement and subjective evaluation of the different regions of the myocardium. The **left ventricular outflow** tract demonstrated normal laminar flow and subjective structural integrity. The **right atrium** and auricle revealed normal size, structure and content. No evidence of masses was noted or chamber overload. **Tricuspid** insufficiency was noted. The **right ventricle** was of normal size (1/3 diameter of LV), chordae structure, myocardial echogenicity and thickness. Slight **pulmonic** insufficiency is noted at 1.6 m/sec.

CANINE CARDIAC PARAMETERS	MR VMAX (m/s)	TR VMAX (m/s)	LA/AO (Boon method)	LA/AO (Heart Base; Swe)	FS (%)	EF (%)	EPSS (cm)

PATIENT		1.15	0.61	7.65	1.8	2.39	

ULTRASONOGRAPHIC FINDINGS

Stage B1 valvular disease with mitral, tricuspid and pulmonic insufficiency.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The insufficiency may be exaggerated owing to sedation particularly in the tricuspid and pulmonic insufficiency.

http://www.sonopath.com/ValveDisease

Description: Myxomatous valvular degeneration refers to a sterile degenerative disease that affects middle-aged and older dogs. The mitral valve apparatus includes the left ventricular papillary muscles, chordae tendinae, valvular annulus, and anterior and posterior leaflets. The anterior leaflet is continuous with the aortic outflow tract. The accumulation of mucopolysaccharides within the spongiosa and fibrosa layers of the leaflets creates a vegetative nodular appearance. This vegetative pathology may also be the result of bacteremia due to dental disease or a different source of bacterial pervasion. Lengthening of the chordae tendinae occurs secondary to any excessive turbulent forces that might transpire. Chondrodystrophic breeds are overrepresented and typically have collapsing trachea and intervertebral disc disease. Cavalier King Charles Spaniels are paradigmatic of this phenomenon; they develop mitral valve disease (MVD) at an early age. MVD prevalence can be as high as 33% in toy breeds over 10 years of age and is the most common cardiac disease in dogs (it accounts for 75-80% of all cases). MVD has also been reported in German Shepherds; they demonstrate a more rapid progression of the disease in comparison to other breeds.

Distortion of the mitral valve leaflets prevents normal cooptation of blood resulting in regurgitative flow of the stroke volume into the left atrium. The lengthening and rupture of the chordae can lead to leaflet prolapse into the atrium and the eventual inversion of the flail leaflet into the atrium, which will in turn exacerbate the regurgitation. Chordae rupture often occurs suddenly, leading to the rapid onset of congestive heart failure (CHF), as the myocardium does not have adequate time to hypertrophy and compensate for the defect. (A small amount of regurgitation can be well tolerated if it progresses more slowly over time.) The result is volume overload of the left atrium and left ventricle, which gives rise to eccentric hypertrophy. Eccentric hypertrophy causes dilation of the mitral annulus, which further complicates the myocardial left atrium and left ventricle stretch. Myocardial oxygen deprivation due to poor coronary perfusion (stretch and catecholamine stimulation) leads to myocardial cell death, replacement fibrosis, and myocardial dysfunction. This pathological progression is known as “overload cardiomyopathy.”

Clinical Signs: The most common sign of MVD is a progressive cough; it is due to left-sided volume overload, which in turn precipitates pulmonary edema and left atrial bulging at the left mainstem bronchus. Respiratory distress ensues gradually in chronic cases or rapidly in cases of primary chordae rupture. Exercise intolerance, syncope, ascites, weight loss, and anorexia are also commonly observed. A physical exam will often reveal an audible murmur best heard over the left cardiac apex. The murmur audibility and length into systole typically corresponds to the degree of mitral regurgitation but not necessarily to the severity of the cardiac status. Concurrent systemic hypertension may induce progression of the disease thereby necessitating systemic blood pressure measurements during medical management.

A challenging situation occurs when the practitioner must determine whether the origin of a cough is respiratory (e.g. tracheal collapse, chronic bronchitis, COPD) or cardiac (e.g. pulmonary edema, mainstem bronchus pressure). A cough history of months or years, normal to high body scores, and normal heart

rates with sinus arrhythmia tend to support chronic airway disease. In cases of MVD, however, the disease tends to be progressive: the body score is lower, the heart rate is higher, and there is a possibility of pathological arrhythmias. Yet, both bronchial disease and MVD can be present simultaneously, and advanced diagnostics, such as ultrasound examination, are necessary to distinguish which culprit is inciting the clinical signs.

Diagnostics: Ascertaining NT-proBNP levels may help to determine whether dyspnea is respiratory or cardiac in origin and provide information that can assist with the early detection of cardiac disease in subclinical patients, especially in high-risk breeds, such as Cavalier King Charles Spaniels, Poodles, and Cocker Spaniels.

Radiographic findings may reveal a vertical or bulging caudal cardiac waist, hilar edema, generalized cardiomegaly, elevation of the left mainstem bronchus, and right-sided enlargement in advanced cases where pulmonary hypertension or tricuspid disease is also present.

Echocardiographic findings allow the practitioner to assess precisely cardiac function under pathological circumstances. Moreover, they enable an evaluation of the myocardial response at the time of the exam and help practitioners continue to quantify that response over time while patients are undergoing therapy.

Treatment: The following treatment options are based on the ACVIM consensus statement regarding MVD.

Stage A: There is a high risk of cardiac disease, but as there are no clinical signs, no specific therapy—medical or dietary—is indicated. A radiograph and an echocardiogram should be conducted in one year or earlier if the patient is a large-breed dog as MVD may progress faster.

Stage B: Heart disease is present.

B1: There is a murmur, but no chamber enlargement. Treatment is the same as for stage A.

B2: There is a murmur with left atrial and left ventricular enlargement, but the patient is asymptomatic. Start angiotensin-converting enzyme (ACE) inhibitors (enalapril at 0.5 mg/kg PO Q12-24hr or benazepril 0.25-0.5 mg/kg PO Q24hr). Consider beta blockers and mild sodium restriction.

Stage C: There are past or current clinical signs of heart failure.

Acute CHF:

- Lasix 2 mg/kg IV or IM hourly to a total dose of 8 mg/kg until the respiratory rate has normalized. Alternatively, for cases of life-threatening pulmonary edema, administer as a CRI (1mg/kg/hour).
- Oxygen supplementation.
- Continue with the ACE inhibitor and add pimobendan at 0.25-0.3 mg/kg PO BID.

Chronic therapy:

- Lasix at 2 mg/kg PO BID and increase incrementally as needed.
- Continue with the ACE inhibitor.
- Pimobendan at 0.25-0.3 mg/kg PO BID.
- Consider adding spironolactone at 0.25-2 mg/kg PO BID to control congestion.
- A sodium-restricted diet is recommended, although some dogs will not eat it.
- Consider administering omega-3 fatty acids, digoxin, theophylline, and cough suppressants.
- If the dog is not already on beta blockers, then do not commence.

Stage D: This is the end-stage of the disease. Continue with the standard therapy of diuretics, ACE inhibitors, and pimobendan, and consider the following:

- Abdominocentesis when applicable to decrease discomfort if the patient is undergoing respiratory distress.
- Anti-anxiety medications for sedative purposes.
- Sodium nitroprusside and dobutamine (in a critical care facility).
- Nitroglycerin.

We recommend monitoring serum urea, creatinine, electrolytes, urine specific gravity, and possibly blood pressure for 5-7 days after therapy has commenced. A repeat ECG is warranted if an arrhythmia was present during the original assessment.
