PRESENTING CLINICAL SIGNS

History: Partial urethral obstruction last month and full this month. Abd rads NSF last month. R/O underlying bladder issue/sludge. Red rubber U-Cath placed.
Bun 51, Creat 2.4 Mon pm @ presentation.

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The **urinary bladder** revealed concentric wall thickening that measured up to 0.5 cm with sand accumulation and regional inflammation. A catheter was present in the bladder in proper position.

The **kidneys** revealed normal size and structure, corticomedullary definition and ratio for this age. The cortices presented largely uniform texture with normal echogenic relationship to liver and spleen. Medullary structure differed distinctly from the cortex and no evidence of pelvic dilation was present. The capsules were acceptably uniform without significant irregularities. The left kidney measured 4.51 cm. The right kidney measured 4.29 cm.

Adrenal Glands

Both **adrenal glands** were visualized and recognized as having normal shape, size, position and echogenicity for this breed. The phrenic vasculature, glandular echogenicity and detail were unremarkable. Capsule, cortex, and medullary definition were normal for this age patient. The left adrenal gland measured 0.48 cm.

Spleen

The **spleen** was mildly enlarged with uniform, but subtly micronodular parenchyma, and undulating capsular contour. The spleen was folded upon itself cranially. This is consistent with reactive spleen owing to immune stimulus or early infiltrative disease such as mast cell disease or lymphoma. 25-gauge FNA would be ideal if weight loss is an issue to differentiate early round cell neoplasia versus splenitis or reactive spleen all of which can present in this manner. The splenic lymph nodes were also enlarged and measured up to 0.5 cm.

Liver

The **liver** images submitted revealed subjectively normal liver size, contour, and structure. Parenchymal echogenicity was naturally coarse and hypoechoic to the spleen. Vascular and biliary tracts were of normal volume with no evidence of congestion. The gallbladder presented acceptably thin walls with primarily anechoic content. The cystic and common bile ducts were normal. No pathological hepatic lymphadenopathy was evident. No overt structural evidence of inflammatory, infiltrative or regenerative pathology was evident.

Gastrointestinal

Examination of the **gastrointestinal tract** revealed a stomach and intestine free of stasis, of normal wall thickness, acceptable curvilinear mural detail, and peristaltic activity. Small and large intestine demonstrated normal luminal chyme and stool consistency respectively. The colon was normal. Slight mesenteric lymphadenopathy was noted and measured 0.5 cm each.

Pancreas

The base and limbs of the **pancreas** were observed to be largely isoechoic to surrounding omental fat. Pancreatic duct and capsular contour were acceptably normal and parenchyma respected normal curvilinear patterns. No overt evidence of active inflammatory or neoplastic disease was noted.

Free Abdomen

Slight free fluid was noted in the abdomen.

ULTRASONOGRAPHIC FINDINGS

Severe cystitis pattern with sand and regional inflammation.

Structurally unremarkable kidneys.

Mild, splenic enlargement.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Acute insult such as that of urinary obstructive disease should be considered as likely history. The slight free fluid may be owing to history of over distension of the urinary bladder wall. Urine culture and sensitivity, 72-hour IV fluid protocol and reassessment of the bladder is recommended to assess if further sand is present or if it dissolves with medical therapy. The spleen and lymph nodes are likely reactive in this patient. FNA can be considered.

Short axis of the urinary bladder in a cat with chronic cystitis. Note the severe thickening and undulating surface of the bladder wall. The regular layers of the urinary bladder wall cannot be discerned (large arrow). There is a moderate amount of echogenic debris seen within the anechoic urine. Mild focal peritonitis is seen as echogenic perivesical fat (small arrow) consistent with adhesion formation stimulated by transmural pathology.

Description: Feline idiopathic cystitis (FIC) is defined as recurrent stranguria and hematuria in cats in the absence of an underlying cause. It is considered to be an exclusionary diagnosis once radiographs, ultrasound, coagulation profile, and aerobic urine culture by cystocentesis have eliminated the possibilities of urinary tract infection, urolithiasis, coagulopathies, and neoplasia. Clinical signs may resolve spontaneously within 3-7 days, with 30-50% recurrence within a year. Cats most frequently acquire the disease between the ages of 2 and 6, and although any breed is susceptible, Persian cats are overrepresented among those affected. Overweight spayed females and neutered males in a multi-cat household are at higher risk than their lean, solitary, or intact counterparts. Indoor, sedentary, dry-food eaters are at higher risk than outdoor cats that eat *ad libitum*. Psychosomatic influences—change of residence, new household members, pet additions, change of household objects—on the urinary bladder have been shown to play an important role in the pathophysiology of the disease. Neurogenic inflammation, decreased glycosaminoglycan concentration, and increased bladder permeability are tissue alterations found on histopathological review of affected bladders. Neurotransmitter P is increased in affected tissue and may be specifically targeted in eventual courses of treatment.

Clinical Signs: In the absence of an underlying urinary tract infection or evidence of neoplasia, FIC may present in an acute or chronic form with the following intermittent lower urinary tract symptoms: inappropriate urination (> 6 times/week in 70% of cases); stranguria (70%); hematuria (50%); and pollakiuria (80%).

Diagnostics: Since FIC is a diagnosis of exclusion, abdominal radiographs, abdominal ultrasound, blood pressure, coagulation profile, and urine culture are all required to rule out other differentials. Biopsy of the bladder wall can be useful to evaluate for lymphocytic plasmacytic inflammation, which can occur in some cases. Taking a history and having a thorough conversation about the cat's environmental stressors are imperative.

Treatment: Given that no specific cause has been cited and that FIC is considered a multifactorial disease, multimodal therapy is recommended. To date, no specific therapeutic has been effective in treating FIC. Palliation with pain management can be achieved with buprenorphine (0.02 mg/kg PO, IM, or IV BID-TID for 3-4 days). Practitioners have attempted the following with varying results: the introduction of a strict canned food diet; a change of feeding location in multi-cat households; and stimulating increased water intake using tuna or clam juice additives or circulating water fountains. To date, the most scientifically valid evidence points to the need for reducing urine concentration, which is achieved with canned food diets. In multiple studies, the simple act of switching to a canned therapeutic diet has been shown to reduce the risk of recurrence significantly. One study showed that only 11% of cats on a canned diet exhibited recurrent signs after a year, while those on a dry food diet displayed a 40% recurrence rate. Urine concentration can be reduced further by adding additional water into servings of canned food. Reduction of stress may be achieved by increasing litter box hygiene, placing

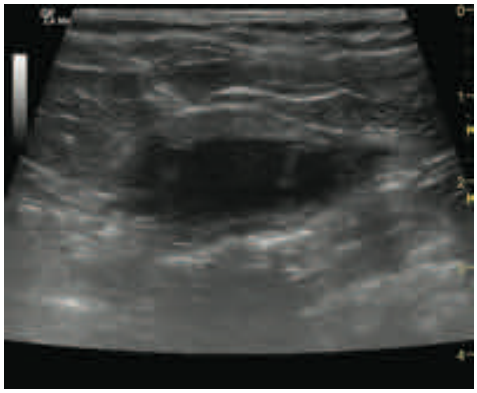
the litter box in a quieter environment, and providing separate food, water, and litter areas for the affected patient in a multi-cat household. It has been suggested that Feliway, the feline facial pheromone, can be used as a calming agent for cats when they are in unfamiliar surroundings. Feliway mimics the natural facial hormone released when a cat marks his or her territory by face rubbing. For unresponsive or severe cases, amitriptyline (10 mg PO Q24hr at bedtime) has been shown to have visceral analgesic, anticholinergic, mucosal mast cell inhibition, and anti-noradrenergic properties. Amitriptyline is considered standard therapy, but is only pursued once the preceding husbandry and feeding practices have proven to be ineffective. Amitriptyline should be used with caution in patients with cardiac disease or arrhythmias, and if instituted, should be used long-term. Studies indicate that short-term use of amitriptyline can result in faster recurrences. Note: Urine retention may occur while therapy is being administered. Biochemical panels should be monitored while a patient is undergoing amitriptyline therapy as liver enzyme elevation can occur. Glycosaminoglycan supplementation (pentosan polysulphate 2-10 mg/kg PO BID) has shown modest success (10-20%) in human trials for idiopathic cystitis. If used, a powder form is recommended to avoid the stress of pill administration (feline Cosequin capsules contain a powder that can be sprinkled onto food). Antiviral agents have not been shown to be effective, and even though researchers have suggested that the concurrent presence of *Calicivirus* may play a role and virus-like particles have been identified in urethral plugs and urine, no adequate evidence of a viral etiology has yet been demonstrated. A double-blind placebo trial suggested that glucocorticoids had no clinical benefits in 12 cases. All cases were self-limiting, in spite of whether the subjects were medicated with corticosteroids or not.

If hematuria seems persistent despite therapy and does not follow a typical FIC pattern (i.e., resolving within one week but recurring within a few weeks), cystoscopy or surgical evaluation may be indicated. Biopsies can be obtained, which allows for histopathology and bladder wall culture.

Environmental enrichment is also important to reduce stress. Providing vertical climbing surfaces, such as cat trees, increasing the number of litter boxes on different floors of the house (the rule of thumb is the number of litter boxes per house should equal the number of cats plus one), and increasing owner attention time, scheduled playtime, as well as supervised outdoor activity can decrease stress for cats.

Conclusion: Effective treatment of FIC involves a multi-modal approach with a strong emphasis on husbandry. Pet owners should focus on the fastidious upkeep of litter boxes and feed their cats canned food to both increase dietary water intake and maintain their cat's lean body weight. Stress management is also key and can be facilitated with environmental enrichment as well as an understanding of feline behavior.



Long axis view of 5-year-old FS feline bladder suffering from clinical signs of hematuria, inappropriate urination and straining. The ventral bladder wall is segmentally thickened. Feline interstitial cystitis is highly variable in presentation and can change sonographically from day to day. This enigma of a disease necessitates further investigation but sonographically, transmural erosion should be monitored as necrosis and perforation can occur.
