PRESENTING CLINICAL SIGNS

Slow progressive weight loss over the last year, 5 lbs within the last month; not eating for 1 week, ultrasound with sonopath march 2025 showed gastric thickening and suspected nodular hyperplasia in liver; dog also has some behavior changes at home, restless, ALP elevated (historical and stable), pupd at home.

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The **urinary bladder**, trigone, and pelvic urethra presented normal thicknesses and normal tone. The ureters were not visible which is normal. No uroliths or sediment were visualized and anechoic urine was present. No evidence of inflammatory or neoplastic changes were noted. Ureteral papillae were normal.

The **kidneys** revealed normal size and structure, corticomedullary definition and ratio for this age. The cortices presented largely uniform texture with normal echogenic relationship to liver and spleen. Medullary structure differed distinctly from the cortex, and no evidence of pelvic dilation was present. The capsules were acceptably uniform without significant irregularities. The left kidney measured 7.6 cm. The right kidney measured 7.77 cm.

Adrenal Glands

The **left adrenal gland** was visualized and recognized as having normal shape, size, position and echogenicity for this breed. The phrenic vasculature, glandular echogenicity and detail were unremarkable. Capsule, cortex, and medullary definition were normal for this age patient. The left adrenal gland measured 0.74 cm.

The **right adrenal gland** was not visualized.

Spleen

The **spleen** was mildly enlarged with subtle micronodular changes.

Liver

The **liver** revealed a microcavitated peripherally inflamed parenchymal and cystic mass, measuring 2.9 cm. The liver was slightly swollen with uniform parenchyma, with the exception of the mass. Increased portal markings were present. The gallbladder and common bile duct were unremarkable.

Gastrointestinal

Examination of the **gastrointestinal tract** revealed a stomach and intestine free of stasis, of normal wall thickness, acceptable curvilinear mural detail, and peristaltic activity. Small and large intestine demonstrated normal luminal chyme and stool consistency respectively. No obstructive or overt infiltrative disease was noted. No associated abnormal lymphatic activity was noted.

Pancreas

The base and limbs of the **pancreas** were observed to be largely isoechoic to surrounding omental fat. Pancreatic duct and capsular contour were acceptably normal and parenchyma respected normal curvilinear patterns. No overt evidence of active inflammatory or neoplastic disease was noted.

ULTRASONOGRAPHIC FINDINGS

- Focal hepatic mass- carcinoma, hemangiosarcoma, nonneoplastic abscessation, or necrosis are all possible.
- Micronodular spleen
- No other evidence of pathology

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

FNA of the spleen and the liver mass with cytology and culture of the mass is indicated. Chest radiographs are warranted to assess for comorbidity or metastatic disease.
