PRESENTING CLINICAL SIGNS

History: Weight loss 5lbs - soft stool consistently. More quiet than usual - not as active - decreased appetite- at least a few months of activity down (lost 16yr old dog about then)
Abnormal PE/Chem/CBC/UA Results: mild thrombocytopenia, lymphopenia - otherwise CBC/chem WNL, no UA or fecal yet

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The **urinary bladder**, trigone, and pelvic urethra presented normal thicknesses and normal tone. The ureters were not visible which is normal. No uroliths or sediment were visualized and anechoic urine was present. No evidence of inflammatory or neoplastic changes was noted. Ureteral papillae were normal.

The **kidneys** revealed normal size and structure, corticomedullary definition and ratio for this age. The cortices presented largely uniform texture with normal echogenic relationship to liver and spleen. Medullary structure differed distinctly from the cortex and no evidence of pelvic dilation was present. The capsules were acceptably uniform without significant irregularities. The left kidney measured 5.3 cm.

Adrenal Glands

The **adrenal glands** were not visualized.

Spleen

The **spleen** was riddled with multiple target nodules/masses. They appear to superimpose the pancreas or concurrent lesions were noted in the pancreas in the cranial abdomen. FNA of the nodules is recommended.

Liver

The visible **liver** appeared normal with uniform parenchyma. The gallbladder and common bile duct were unremarkable.

Gastrointestinal

Examination of the **gastrointestinal tract** revealed a stomach and intestine free of stasis, of normal wall thickness, acceptable curvilinear mural detail, and peristaltic activity. Small and large intestine demonstrated normal luminal chyme and stool consistency respectively. Lymph nodes were enlarged, and irregular.

PATIENT

Pancreas

Jedda Bingham

The base and limbs of the **pancreas** were observed to be largely isoechoic to surrounding omental fat. Pancreatic duct and capsular contour were acceptably normal and parenchyma respected normal curvilinear patterns. No overt evidence of active inflammatory or neoplastic disease was noted.

SPECIES

Canine

Heart

BREED

Border Collie

Rapid view of the heart revealed no evidence of pathology.

SEX

Spayed female

Splenic target nodules/masses, Appears to superimpose the pancreas or concurrent lesions were noted in the pancreas in the cranial abdomen

Enlarged lymph nodes.

AGE

6 years

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

CT evaluation would be ideal for further definition or direct exploratory surgery. Round cell neoplasia or other neoplasia is suspected. There is a minor potential for granulomatous/fungal disease.
