DATE

8/26/22

PRESENTING CLINICAL SIGNS

History: Found subcutaneous hemangiosarcoma. Overall healthy. Survey for internal tumors.

Abnormal PE/Chem/CBC/UA Results: WNL

The exam was limited to the intestines, spleen, left kidney and urinary bladder. 36 videos were submitted.

LIMITED ULTRASONOGRAPHIC EXAMINATION

Urinary System

The **urinary bladder**, trigone, and pelvic urethra presented normal thicknesses and normal tone. The ureters were not visible which is normal. No uroliths or sediment were visualized, and anechoic urine was present. No evidence of inflammatory or neoplastic changes were noted. Ureteral papillae were normal.

The **left kidney** revealed normal size and structure, corticomedullary definition and ratio for this age. The cortices presented largely uniform texture with normal echogenic relationship to liver and spleen. Medullary structure differed distinctly from the cortex and no evidence of pelvic dilation was present. The capsules were acceptably uniform without significant irregularities.

Spleen

The **spleen** revealed subtle hypoechoic nodular changes, nondisruptive without capsular expansion. Cranial folding of the spleen was noted.

Gastrointestinal

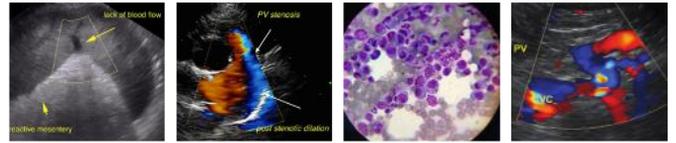

Examination of the **gastrointestinal tract** revealed a stomach and intestine free of stasis, of normal wall thickness, acceptable curvilinear mural detail, and peristaltic activity. Small and large intestine demonstrated normal luminal chyme and stool consistency respectively. No obstructive or overt infiltrative disease was noted. No associated abnormal lymphatic activity was noted.

ULTRASONOGRAPHIC FINDINGS

- Nodular hyperplasia splenic pattern

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

In the image set provided, no overt evidence of primary or secondary neoplasia noted, however, mild nodular hyperplasia splenic pattern was noted. Full abdominal sonogram is recommended to ensure other organ systems are not involved. 25-gauge FNA of the spleen could be considered to confirm suspicion of hyperplasia.
