PRESENTING CLINICAL SIGNS

Follow up kidney and liver

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The **urinary bladder** revealed a mural lesion that measured 1.3 cm in the dorsal apical wall. This was similar to the prior sonogram.

The **kidneys** revealed normal size and structure, corticomedullary definition and ratio for this age. The cortices presented largely uniform texture with normal echogenic relationship to liver and spleen. Medullary structure differed distinctly from the cortex. The capsules were acceptably uniform without significant irregularities. Pyelectasia is noted in the left kidney. The right kidney measured 4.38 cm.

Adrenal Glands

Both **adrenal glands** were visualized and recognized as having normal shape, size, position and echogenicity for this breed. The phrenic vasculature, glandular echogenicity and detail were unremarkable. Capsule, cortex, and medullary definition were normal for this age patient. The left adrenal gland measured 1.94 x 0.63 cm at the caudal pole and 0.57 cm at the cranial pole. The right adrenal gland measured 1.96 x 0.79 cm.

Spleen

The **spleen** in this patient was mildly enlarged with uniform parenchyma and was folded upon itself cranially. This is a positional variant and is not pathological. There was no evidence of significant disease.

Liver

The **liver** revealed two separate echogenic nodular masses in the mid cranial liver and left cranial liver measuring 5.0 x 2.0 cm. The mass deviated the diaphragm. The right cranial liver mass measured 4.6 cm with hyperechoic surrounding fat. There were areas of necrosis and a trace amount of free fluid. Vascular and biliary tracts were of normal volume with no evidence of congestion. The gallbladder presented acceptably thin walls with primarily anechoic content. The cystic and common bile ducts were normal.

Gastrointestinal

Examination of the **gastrointestinal tract** revealed a stomach and intestine free of stasis, of normal wall thickness, acceptable curvilinear mural detail, and peristaltic activity. Small and large intestine demonstrated normal luminal chyme and stool consistency respectively. No obstructive or overt infiltrative disease was noted. No associated abnormal lymphatic activity was noted.

Pancreas

The base and limbs of the **pancreas** were observed to be largely isoechoic to surrounding omental fat. Pancreatic duct and capsular contour were acceptably normal and parenchyma respected normal curvilinear patterns. No overt evidence of active inflammatory or neoplastic disease was noted.

Free Abdomen

The left cranial abdomen revealed an undifferentiated 6.6 x 4.0 cm hypoechoic nodular mass with regional, hyperechoic surrounding inflammation. This is strongly consistent with sarcoma.

ULTRASONOGRAPHIC FINDINGS

- Progressive, multi-centric sarcomatous type liver or neoplasia involving the left cranial abdominal mass. Likely of lymph node origin.
- Multiple liver masses.
- Mural bladder mass, stable.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Oncological intervention is recommended. Prognosis is guarded to poor.
