PRESENTING CLINICAL SIGNS

- 13 yr old spayed female cat. she is sedated with dkt. reason of abdominal ultrasound is that she has been losing weight for the past 6 months (1.3 lbs) and loss of appetite. Pasha appears to be uncomfortable per the owner. did comprehensive blood work including fpli and thyroid - all normal. urine is diluted (1.017)

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The bladder is moderately distended with anechoic urine. No uroliths are seen. The bladder wall is normal in appearance and thickness. No masses are seen.

The left kidney presents normal size with normal shape and architecture. Mild loss of corticomedullary distinction. No pyelectasia, ureteral dilation or nephrolithiasis. The left kidney measured 3.6 cm in length.

The right kidney presents normal size with normal shape and architecture. Mild loss of corticomedullary distinction. No pyelectasia, ureteral dilation or nephrolithiasis. The right kidney measured 3.3 cm in length.

Adrenal Glands

The left adrenal gland presents normal shape and homogenous parenchyma. The phrenic vasculature is unremarkable. The cranial pole measures 3.4 mm in width.

The right adrenal gland presents normal shape and homogenous parenchyma. The phrenic vasculature is unremarkable. The cranial pole measures 3.6 mm in width.

Spleen

The spleen is normal in size, shape, margination and echogenicity. There are several hyperechoic lesions throughout the spleen consistent with benign myelolipomas. A representative splenic lesion measured 1.6 mm in width.

Liver

The liver appears to be mildly diffusely enlarged and to have a mildly diffused hyperechoic echotexture with rounded margins.

The gallbladder presents normal size with anechoic contents. Normal gallbladder wall. No evidence of bile duct distention or obstruction.

Gastrointestinal

The stomach has normal wall layering and thickness. Colon contains normal contents with normal wall thickness. The jejunum diffusely is normal in thickness at 2.0 mm and has normal layering present.

Pancreas

The visible pancreas is normal in size with normal echogenic parenchyma and surrounded by normal peri-pancreatic mesentery. This presentation is consistent with the reportedly normal fPLI that was performed by the primary care veterinarian.

Free Abdomen

There are no enlarged abdominal lymph nodes seen on this exam. No free abdominal fluid is seen.

ULTRASONOGRAPHIC FINDINGS

- Bilateral decreased corticomedullary distinction.
- Enlarged hyperechoic liver consistent with vacuolar hepatopathy most likely due to early hepatic lipidosis from the patient's reported loss of appetite and weight loss.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Given that the patient is reported to have dilute urine (urine specific gravity of 1.017), early chronic kidney disease is suspected. Recommend full staging, monitoring and managing the patient for the international renal interest study guidelines. No specific cause for the patient's weight loss and decreased appetite is seen on this ultrasound. Recommend performing a more global search for the patient's primary problem. Consider orthopedic disease. Recommend three view chest x-rays to rule out any evidence of thoracic/pulmonary disease. If a recent FELV/FIV test has not been performed, recommend performing for testing.
