RADIOGRAPHIC STUDY OF THE THORAX

The body condition score is 6/9.

The bony structures appear physiological for the given age.

SEX

Neutered Male

The lungs are in contact with the thoracic boundaries and the tips are pointed. The lobar vessels are visible. On the VD view the right caudal lobar vessel are poorly outlined. The left scapula is superimposed onto the cranial lung lobe which results in an increased opacity at this level.

AGE

1 Year

The cranial mediastinum is of physiological size and opacity. The trachea diverges from the thoracic vertebrae and the carina is located at T5.

The cardiac is raised from the sternum by a small amount of fat. Its silhouette occupies 75% of the chest height and 3 intercostal spaces (VHS 11). No chamber or outflow tract enlargement is evident.

RADIOGRAPHIC DIAGNOSIS

INTERPRETED BY

Heike Rudorf, DVM,
Dr. med. Vet.,
DipECVDI DVR

- Interstitial pattern right caudal lobe

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

HOSPITAL NAME

Petworks VH

The interstitial pattern in the right caudal lobe is most likely the result of a technical artefact (e.g. no grid lines) rather than due to a true infiltrate. A comparison with the previous radiographs is recommended. The breathing difficulties could be the result of inflamed upper respiratory tract mucosa due to the vomiting; visual inspection is recommended.

REFERRING VET

Dr. Trudeau

A CT examination is recommended to rule out an underlying nasal disease such as foreign body.
