**PRESENTING CLINICAL SIGNS**

P presented for US due to chronic vomiting. Improved on Cerenia but now back to vomiting multiple times per day. Bloodwork unremarkable

**ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN**

**Urinary System**

The urinary bladder is moderately distended with anechoic urine. The Bladder wall, trigone, ureteral papillae and visible urethra (to a depth of 2cm) appear normal with no evidence of wall thickening, mucosal irregularities, masses or cystic calculi.

The left kidney has a normal shape and size (3.47 cm). Overall echogenicity is normal with adequate corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of focal perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

The right kidney has a normal shape and size (4.12 cm). Overall echogenicity is normal with adequate corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of focal perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

**Adrenal Glands**

The left adrenal gland is normal in size measuring 0.30 cm at the caudal pole. It is observed in its normal position cranial to the left renal artery. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

The right adrenal gland is normal in size measuring 0.51 cm at the caudal pole. It is observed in its normal position between the cranial aspect of the right kidney and the caudal vena cava. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

**Spleen**

The spleen is subjectively normal in size (0.71 cm), echotexture is homogenous, and the splenic capsule is smooth with no irregularities. The blood flow through the hilus and splenic parenchyma appears normal. No focal parenchymal abnormalities are visualized.

**Liver**

The liver is subjectively normal in size, and echogenicity with smooth peripheral margins. The parenchyma is homogenous echotexture. The visible portions of the vasculature and biliary tract appear normal. No focal nodules or cystic lesions are observed.

The gall bladder lumen is moderately distended. The wall of the gall bladder is not thickened and has a smooth mucosal surface. Luminal contents are mild and likely incidental at this time. The cystic and common bile ducts are normal/not visible.

***Gastrointestinal***

The stomach contains mild fluid. The gastric wall appears normal in some regions with intact wall layering and normal rugal folding, measuring at 0.40 cm. There is a focal section of gastric wall that appears severely thickened with reduced detail of wall layering. In this area the gastric wall measures at 0.15 cm. No evidence of an outflow tract obstruction is visualized.

The visualized areas of duodenum, jejunum and ileum have a relatively uniform diameter with minimal fluid distension. Wall thickness is normal. Bowel loops follow a curvilinear path with distinct wall layering maintaining the typical 1:3 muscularis:mucosa layer ratio. Duodenum wall measures 0.19 cm. Jejunum wall measures 0.18 cm. Visualized peristalsis appears appropriate. There were no focal lesions consistent with obstruction or a mass effect observed.

The ileocecal junction was visualized and exhibited normal intact wall layering and is subjectively of normal thickness. Sections of colon are visualized with formed fecal material and gas shadowing distally. There is no observed focal or generalized colon wall thickening or loss of layering.

***Pancreas***

The pancreas is normal and isoechoic to surrounding mesentery. There is no evidence of nodules or cystic lesions. There is no evidence of regional mesenteric inflammation or fluid.

***Free Abdomen***

Evaluation of the peritoneal cavity did not reveal any evidence of effusion. There is no evidence of a significant diffuse lymphadenopathy. There is an enlarged cranial abdominal/gastric lymph node measuring 0.42 cm x 1.02 cm. The omentum is slightly hyperechoic in the cranial abdomen around the stomach.

**ULTRASONOGRAPHIC FINDINGS**

- Focal thickening and loss of layering of the gastric wall – Findings are concerning for infiltrative disease (round cell neoplasia, carcinoma, other). Severe gastritis is possible.
- Prominent gastric lymph node – Findings are most consistent with highly reactive or metastatic lymph node.

**INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS**

There is focal thickening of the gastric wall. These changes could be concerning for early infiltrative neoplasia, although other differentials such as severe gastritis, eosinophilic infiltrates, etc. are possible. Recommend a fine needle aspirate of the gastric wall to further evaluate.
