PRESENTING CLINICAL SIGNS

P presented for US due to acute vomiting on Friday. ALT increased previously in the 200's now in the 600's. P still nauseous but overall better Liver appears small on rads

ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Urinary System

The urinary bladder is moderately distended with anechoic urine. The Bladder wall, trigone, ureteral papillae and visible urethra (to a depth of 2cm) appear normal with no evidence of wall thickening, mucosal irregularities, masses or cystic calculi.

The left kidney has a normal shape and size (6.85 cm). Overall echogenicity is normal with adequate corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of focal perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

The right kidney has a normal shape and size (6.29 cm). Overall echogenicity is normal with adequate corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of focal perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

Adrenal Glands

The left adrenal gland is normal/borderline "flat" measuring 0.42 cm at the cranial pole and 0.41 cm at the caudal pole. It is observed in its normal position cranial to the left renal artery. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

The right adrenal gland is normal/borderline "flat" measuring 0.53 cm at the cranial pole and 0.46 cm at the caudal pole. It is observed in its normal position between the cranial aspect of the right kidney and the caudal vena cava. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

Spleen

The spleen is subjectively normal in size (2.49 cm), echotexture is homogenous, and the splenic capsule is smooth with no irregularities. The blood flow through the hilus and splenic parenchyma appears normal. No focal parenchymal abnormalities are visualized.

Liver

The liver is normal/borderline small. The parenchyma is homogenous echotexture. The visible portions of the vasculature and biliary tract appear normal. No focal nodules or cystic lesions are observed.

The gall bladder lumen is moderately distended. The wall of the gall bladder is not thickened and has a smooth mucosal surface. Luminal contents are mild and likely incidental at this time. The cystic and common bile ducts are normal/not visible.

Gastrointestinal

The stomach contains moderate shadowing ingesta. It measures at a normal thickness of <0.7cm with some variability due to the presence of rugal folds. The distinction of the gastric wall layers is adequate

and there is no impression of reduced peristaltic activity. Shadowing ingesta interferes with full evaluation of the stomach and some areas of the cranial abdomen.

The visualized areas of duodenum, jejunum and ileum have a relatively uniform diameter with minimal fluid distension. Wall thickness is normal. Bowel loops follow a curvilinear path with distinct wall layering maintaining the typical 1:3 muscularis:mucosa layer ratio. Jejunum wall measures 0.32 cm. Visualized peristalsis appears appropriate. There were no focal lesions consistent with obstruction or a mass effect observed.

Sections of colon are visualized with formed fecal material and gas shadowing distally. There is no observed focal or generalized colon wall thickening or loss of layering.

Pancreas

The area of the pancreas is normal and isoechoic to surrounding mesentery. There is no evidence of nodules or cystic lesions. There is no evidence of regional mesenteric inflammation or fluid.

Free Abdomen

Evaluation of the peritoneal cavity did not reveal any evidence of effusion, or subjective lymphadenomegaly. The Medial iliac nodes appear normal and there was no evidence of a caudal aortic thrombus at the bifurcation. The omentum is of normal uniform echogenicity.

ULTRASONOGRAPHIC FINDINGS

- Borderline “flat” adrenal glands – Consider a screening baseline cortisol.
- Normal/borderline small liver- Correlate with radiographs to better assess size.
- Shadowing ingesta visualized within the gastric lumen – Correlate with feeding history. If the patient is adequately fasted, consider the possibility of delayed gastric emptying, ingested foreign material, less likely an outflow tract obstruction (none visualized).

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

No focal lesions are visualized associated with the liver or gallbladder to explain the elevation in ALT reported. Subjectively, the liver appears somewhat small. Correlate with liver size on radiographs and recommend pre- and post-prandial bile acids to assess liver function. If bile acids are severely elevated (>80), you could consider a contrast CT scan if a liver shunt is a concern. Additionally, consider a biopsy of the liver with samples for histopathology, culture and copper levels. Prior to this, consider screening for Leptospirosis if clinically appropriate.

The recent elevation in liver enzymes could also be reactive secondary to whatever has caused the GI upset. If this is improving, consider repeating liver values in 1-2 weeks once the symptoms have fully subsided.

There is shadowing material visualized within the gastric lumen. If the patient was adequately fasted, this could represent delayed gastric emptying, retained foreign material, etc. If further evaluation is desired, you could consider an upper GI endoscopy.
