**DATE**

5/6/22

**PRESENTING CLINICAL SIGNS**

Patient presents for not eating well, intermittent vomiting, and pancreatitis. Current meds: Cerenia and Convenia injectable.

Abnormal PE/Chem/CBC/UA Results: Pancreatic lipase immuno 5.8, amylase 1333, platelets 293, MPV 13.8, PCT 0.40%, PDWc 42.7%, PDWs 23.9.

**ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN**

**Urinary System**

The urinary bladder is moderately distended with anechoic urine. The Bladder wall, trigone, ureteral papillae and visible urethra (to a depth of 2cm) appear normal with no evidence of wall thickening, mucosal irregularities, masses or cystic calculi.

The left kidney has a normal shape and size (3.58 cm). Overall echogenicity is slightly hyperechoic with poor corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

The right kidney has a normal shape and size (3.2 cm). Overall echogenicity is slightly hyperechoic with poor corticomedullary distinction and a typical 1:3 cortex:medulla ratio. There is no evidence of perinephric inflammation or effusion. There is no evidence of pyelectasia, nephroliths, infarcts or hydroureter. Renal vasculature is normal.

**Adrenal Glands**

The left adrenal gland is normal in size measuring 0.27 cm at the caudal pole. It is observed in its normal position cranial to the left renal artery. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

The right adrenal gland is normal in size measuring 0.26 cm at the caudal pole. It is observed in its normal position between the cranial aspect of the right kidney and the caudal vena cava. It is normal in appearance (uniformly hypoechoic) and shape with no evidence of a mass effect.

**Spleen**

The spleen is large in size (1.11 cm in width at the level of the hilus). The spleen echotexture is heterogenous and mottled, the splenic capsule is smooth with no irregularities. The blood flow through the hilus and splenic parenchyma appears normal. No focal parenchymal abnormalities are visualized.

**Liver**

The liver is subjectively normal in size, and echogenicity with smooth peripheral margins. The parenchyma is homogenous echotexture. The visible portions of the vasculature and biliary tract appear normal. No focal nodules or cystic lesions are observed.

The gallbladder lumen is moderately distended. The wall of the gall bladder is not thickened and has a smooth mucosal surface. Luminal contents are primarily anechoic. The cystic and common bile ducts are normal/not visible.

**Gastrointestinal**

The stomach contains minimal luminal contents. It measures at a normal thickness of <0.36cm with some variability due to the presence of rugal folds. The distinction of the gastric wall layers is

**PATIENT**

Pebbles Scalone

adequate and there is no impression of reduced peristaltic activity. No masses or focal lesions were observed.

**SPECIES**

Feline

The visualized areas of duodenum, jejunum and ileum have a relatively uniform diameter with minimal fluid distension. Wall thickness is normal. Bowel loops follow a curvilinear path with distinct wall layering maintaining the typical 1:3 muscularis:mucosa layer ratio. The duodenum measured as normal (between 0.13-0.38cm in wall thickness) and the jejunum measured as normal (between 0.15-0.36cm.) Visualized peristalsis appears appropriate. There were no focal lesions consistent with obstruction or a mass effect observed.

**BREED**

DSH

The ileocecal junction was visualized and exhibited normal intact wall layering and is subjectively of normal thickness. Sections of colon are visualized with formed fecal material and gas shadowing distally. There is no observed focal or generalized colon wall thickening or loss of layering.

**SEX**

Spayed Female

**Pancreas**

The pancreas is prominent and mildly mottled compared to the surrounding isoechoic mesentery. There is no evidence of nodules or cystic lesions. There is no evidence of regional mesenteric inflammation or fluid.

**AGE**

16 Years

**Free Abdomen**

Evaluation of the peritoneal cavity did not reveal any evidence of effusion, or subjective lymphadenomegaly. The Medial iliac nodes appear normal and there was no evidence of a caudal aortic thrombus at the bifurcation. The omentum is of normal uniform echogenicity.

**WEIGHT**

11.6 Pounds

**ULTRASONOGRAPHIC FINDINGS**

- Borderline large, mottled spleen – The diffuse splenic changes are non-specific and could be consistent with lymphoid hyperplasia, extramedullary hematopoiesis, infiltrative neoplasia, inflammation, other. Cytology or histopathology would be necessary to get a definitive diagnosis. There are no focal lesions observed in the spleen, and changes are very subtle.
- Mildly mottled pancreas – Changes are very subtle and likely within normal limits. There is discomfort noted when imaging over the pancreas.
- Decreased corticomedullary distinction in both kidneys – Mild loss of corticomedullary distinction in both kidneys could be consistent with chronic degenerative disease or interstitial nephrosis.

**INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS**

The changes observed on today's scan were all very mild and subtle. Many of these changes can be normal for an older cat. The spleen appears somewhat irregular, mottled, and large. I suspect much of this is due to it mildly deviating in position (it has a slight bend), but a fine needle aspirate could be considered.

**REFERRING VET**

Dr. Marisa Herzog

The pancreas does not appear prominent and is actually difficult to visualize, but there is pain reported on imaging over it, and there is not always a strong correlation between the appearance of the pancreas on ultrasound and clinical signs associated with pancreatitis. If a quantitative fPLI is elevated (I believe it is), then I would recommend treatment for pancreatitis.

**INVOICE**

37430

There is decreased corticomedullary distinction in both kidneys. Much of this is likely chronic age related changes. Consider urinalysis, urine culture and blood pressure evaluation to obtain a baseline.

**DATE**

5/6/22

**PATIENT**

Pebbles Scalone

There is no evidence of bowel dilation or foreign material, although some types of foreign material can be difficult to identify with ultrasound. Correlate with abdominal radiographs and serial imaging if symptoms persist.

**SPECIES**

Feline

Recommend 3-view thoracic radiographs to evaluate for concurrent intrathoracic disease.
