PRESENTING CLINICAL SIGNS

Limping left hind

RADIOGRAPHIC STUDY OF THE PELVIS

Radiographs of the pelvis in one imaging plane are provided for review.

RADIOGRAPHIC FINDINGS

The hip joints are mildly incongruent.

The femoral heads are mildly remodeled and there is mild sclerosis in the acetabulum, bilaterally.

The patellae are laterally displaced due to positioning, and the stifle joints are unremarkable in the view provided.

The soft tissues are unremarkable.

RADIOGRAPHIC DIAGNOSIS

- Mild degenerative joint disease of the hips, secondary to hip dysplasia.

INTERPRETATION OF FINDINGS & FURTHER RECOMMENDATIONS

Mild-to-moderate hip dysplasia is present. Although this finding may contribute to chronic stiffness, decreased activity, or discomfort, hip dysplasia does not typically result in acute or pronounced unilateral hindlimb lameness. Therefore, the reported left hindlimb limping is likely attributable to another orthopedic condition – cranial cruciate ligament injury is a common cause. Correlation with orthopedic examination findings is recommended. Consider left stifle focused radiographs as clinically indicated. Conservative management of hip dysplasia, including weight management, controlled exercise, rehabilitation therapy, and analgesic therapy as clinically indicated, may also be considered.
