The submitted study contained 11 videos of the liver.

PRESENTING CLINICAL SIGNS

Follow-up ultrasound monitoring liver nodules identified 11/12/25 (invoice 71736)

Cat takes Fluoxetine

LIMITED ULTRASONOGRAPHIC EXAMINATION OF THE ABDOMEN

Liver/Gallbladder

Borderline to potential mild hepatomegaly subjectively with maintained symmetrical contour. Mild non-homogenous to potential mild increased generalized hepatic parenchyma exhibiting focal to intermittent discreet hypoechoic to non-homogenous intraparenchymal nodules. An example measured 1.1 cm in diameter, similar in size compared to the previous study.

The gallbladder was non-distended in size with thin walls and mild debris in the area of the gallbladder neck. The cystic and common bile ducts were normal.

ULTRASONOGRAPHIC FINDINGS

Primary

- Borderline to possible mild hepatomegaly with subjective static intraparenchymal nodules
- Mild gallbladder debris

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Correlation with assessment of hepatic enzyme levels is recommended. The nodules and overall liver may indicate benign criteria, i.e. hyperplasia, hematopoiesis, inflammation, etc. with neoplastic criteria thought less likely given overall static presentation of the nodules yet not definitively excluded.

If normal clotting status and using a 25ga needle, hepatic parenchyma and nodule FNA cytology is warranted for further clarification.
