PRESENTING CLINICAL SIGNS

History:

- coughed and vomited bile , no hm , no weight loss (hx of acid reflux)

Abnormal PE/Chem/CBC/UA Results: wnl

RADIOGRAPHIC STUDY OF THE THORAX

Right/left lateral and ventrodorsal views of the thorax totaling 3 images available for review.

RADIOGRAPHIC FINDINGS

A solitary soft tissue opaque mass measuring approximately 4.5 cm is located in the right caudal lung lobe. No additional pulmonary nodules are identified radiographically. The lung parenchyma appears consistent with expected age related changes.

No evidence of thoracic lymphadenopathy is observed.

The cardiac silhouette appears within normal limits for age.

There is no evidence of pleural effusion.

Mild age related spondylosis is present at T5 – T8 and T9/10.

RADIOGRAPHIC DIAGNOSIS

- Solitary pulmonary soft tissue mass in the right caudal lobe – most likely neoplastic in nature.
- No additional nodules seen.
- Thoracic spondyloses.

INTERPRETATION OF FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study reveals a solitary pulmonary mass in the right caudal lobe. The findings are compatible with primary pulmonary neoplasia such as bronchogenic carcinoma or adenocarcinoma. Metastatic pulmonary nodule and focal granuloma are considered less likely but can never be ruled out entirely. Evidence of metastatic disease is not seen radiographically.

Thoracic CT can be performed to facilitate surgical planning and rule out presence of interstitial nodules below the threshold of radiographs. Abdominal imaging could be considered to further workup the GI signs and rule out primary neoplasia elsewhere. Surgical consultation for lobectomy of the right caudal lung lobe is indicated if the patient is a suitable surgical candidate and no other lesions are found.
