

**PATIENT**

Rosey Logan

PRESENTING CLINICAL SIGNS

Intermittent mild left forelimb lameness for about a two week duration. No familial history of elbow dysplasia per owner. No obvious abnormalities on physical examination except slightly reduced weight bearing on left forelimb.

SPECIES

Canine

Abnormal PE/Chem/CBC/UA Results: N/A

RADIOGRAPHIC STUDY OF THE ELBOWS

Flexed mediolateral and craniocaudal views of both elbows totaling 4 images available for review.

BREED

Labrador Retriever

RADIOGRAPHIC FINDINGS

There is an isolated anconeal process in both elbows with radiolucent gap between the apophyseal ossification center of the anconeal process and olecranon. Deep peripheral sclerosis of the olecranon is noted bilaterally.

SEX

Female

Deformity and blurring of the cranioproximal contour of the medial coronoid process is present in both elbows. Bilateral subtrochlear notch sclerosis of the ulnar is seen.

AGE

8 Months

Both elbows present moderate secondary osteoarthritic changes.

INTERPRETED BY

Nele Eley, DVM
Dr. med. Vet. DipECVDI

- Bilateral elbow dysplasia with isolated anconeal process and medial coronoid pathology as well as moderate secondary osteoarthritis in both elbows.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

An isolated anconeal process and radiographic evidence of medial coronoid pathology are noted in both elbows. Both elbows present moderate secondary osteoarthritic changes despite the patient's young age as a consequence of elbow dysplasia. Surgical intervention should be considered in both elbows in order to prevent further damage to the articular structures. Surgery may be preceded by CT depending on the surgeon's preference.
