PRESENTING CLINICAL SIGNS

- Right front lameness
- r/o sprain vs djd vs cervical

RADIOGRAPHIC STUDY OF THE BILATERAL SHOULDERS

Mediolateral and craniocaudal views of both shoulders totaling 4 images available for review.

RADIOGRAPHIC FINDINGS

Normal bony alignment of the glenohumeral joint is seen in both shoulders. The contours of the humeral head are intact and smooth. The glenoid, acromion, and visible parts of the scapula present within normal limits. The joint spaces are maintained. No subchondral bone defects or periarticular new bone formation is seen. There is no evidence of fractures, luxation, or subluxation. No evidence of aggressive bone disease is noted.

RADIOGRAPHIC DIAGNOSIS

- Radiographically normal bilateral shoulders.

INTERPRETATION OF FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study reveals no evidence of fracture, luxation, or degenerative joint disease. The right front lameness is not attributable to radiographic shoulder pathology. Potential causes include soft tissue injury in the in the biceps, rotator cuff, or other soft tissue structure of the shoulder as well as cervical, neurologic, or other origin. Advanced imaging such as MRI with greater soft tissue sensitivity of the shoulder and/or spine could be considered depending on the clinical correlation.
