RADIOGRAPHIC FINDINGS

The degree of pulmonary inflation is deep. Multiple small soft tissue opaque interstitial pulmonary nodules and mostly evenly distributed throughout the entire lung field. Mild peribronchial cuffing is seen in the caudodorsal lung field.

AGE

9 Years

Course and width of the trachea are considered within normal limits.

INTERPRETED BY

Nele Eley, DVM
Dr. med. Vet. DipECVDI

The cardiac silhouette presents within normal limits. No evidence of generalized cardiomegaly or specific chamber enlargement is noted. The pulmonary vessels are thin.

Mild gastric aerophagia is present.

HOSPITAL NAME

The Collegeway
Animal Hospital

RADIOGRAPHIC DIAGNOSIS

- Miliary to multinodular interstitial lung pattern.

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study reveals multiple miliary and small nodules within the pulmonary interstitium which are evenly distributed throughout all lung lobes. Differential diagnosis includes secondary neoplasia of the lung such as metastases of an undetermined primary tumor primarily. Eosinophilic granuloma and pneumonic nodules cannot be ruled out entirely but are by far less likely. Screening for a primary tumor by means of abdominal ultrasound could be considered if not performed already. Fine needle aspiration of nodules within the pulmonary periphery under ultrasonographic guidance could be considered for further definition after ensuring functional coagulation.
