

**PATIENT**

Moose Dattolo

PRESENTING CLINICAL SIGNS

Left thoracic limb lameness of 6 months

SPECIES

Canine

RADIOGRAPHIC STUDY OF THE LEFT ELBOW

Mediolateral and craniocaudal views of the left elbow totaling 3 images available for review.

BREED

Labrador Retriever

There appears to be significant articular enlargement of the left elbow joint.

SEX

Male Neutered

Blurring and decreased opacity of the cranial contour of the medial coronoid process are seen. There is a mild radioulnar step formation.

A large amount of smooth periarticular osteophytes is seen accentuating the humeral epicondyles, anconeus process, and radial head.

AGE

11 Years

The medial joint compartment is narrow.

Sclerosis of the subchondral bone of the medial humeral condyle is seen.

The muscle volume of the left thoracic limb appears to be relatively low.

INTERPRETED BYNele Eley, DVM
Dr. med. Vet. DipECVDI**RADIOGRAPHIC DIAGNOSIS**

- Chronic (end stage) degenerative joint disease of the left elbow secondary to medial coronoid pathology with suspect medial compartment syndrome.
- Articular enlargement of the left elbow.
- Disuse atrophy of the left thoracic limb musculature.

HOSPITAL NAMEAnimal Surgical
Center**INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS**

The radiographic study reveals left elbow dysplasia in terms of medial coronoid pathology with severe chronic secondary osteoarthritis of the left elbow and suspect medial compartment syndrome. The articular enlargement may be due to the osteoarthritis. Other articular enlargement including synovial neoplasia can never be ruled out entirely. However, no direct radiographic signs of aggressive bone lysis are seen.
