

**PATIENT**

Bean Gigone

**PRESENTING CLINICAL SIGNS**

Non weight bearing on right hind leg since friday adter a jump  
Abnormal PE/Chem/CBC/UA Results: Clicking sound with flexion and extension of right knee

**SPECIES**

Canine

**RADIOGRAPHIC STUDY OF THE RIGHT STIFLE**

Mediolateral and craniocaudal view of the right stifle on hip extended ventrodorsal view of the pelvis totaling 3 images available for review.

**BREED**

Yorkshire Terrier

**RADIOGRAPHIC FINDINGS**

Sever subluxation of the right tibia with respect to the femur is seen. There is moderate articular swelling as well as a moderate amount of periarticular osteophytes accentuating the distal pole of the patella and femoral trochlea. The patella is in situ on the orthogonal view.

**SEX**

Neutered Male

Mild muscle atrophy of the right hind limbs is noted.

**AGE**

8 Years

**RADIOGRAPHIC DIAGNOSIS**

- Mild to moderate osteoarthritis of the right stifle with radiographic evidence of cranial cruciate ligament failure.
- Mild disuse atrophy of the right hind limb musculature.

**INTERPRETED BY**

Nele Eley, DVM  
Dr. med. Vet. DipECVDI

**INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS**

The severe subluxation of the right tibia is due to failure of the cranial cruciate ligament. Complete rupture is considered most likely however partial rupture and elongation cannot be ruled out entirely even though considered by far less likely. Based on the severe degree of subluxation, concurrent meniscopthy cannot be ruled out. Consider surgical intervention in order to address the presumed biomechanical instability of the right stifle joint and prevent further damage to the articular structures.
