PRESENTING CLINICAL SIGNS

Gagging, Regurgitation and reflux
Abnormal PE/Chem/CBC/UA Results: No Issues

SPECIES

Canine

RADIOGRAPHIC STUDY OF THE NECK & THORAX

Barium esophagogram in lateral and dorsoventral views totaling 3 images available for review.

BREED

Goldendoodle

RADIOGRAPHIC FINDINGS

Longitudinal mucosal folds are seen throughout the cervical and cranial thoracic thorax. A formed bolus is seen level with the heart base. No evidence of abnormal dilation of the esophagus is seen throughout the study.

SEX

Male

I presume the esophagogram with fluid is the first one and the second is contrast media mixed with kibble; none of which presents evidence of stricture, dilation, diverticulum, or displacement.

AGE

16 Weeks

A thin layer of contrast media appears to cover the laryngopharynx.

The visible lung presents within age related normal limits. No evidence of aspiration pneumonia is seen.

A thymic remnant is seen in the cranioventral mediastinum.

INTERPRETED BY

Nele Eley, DVM
Dr. med. Vet. DipECVDI

The stomach contains a large amount of positive contrast media.

RADIOGRAPHIC DIAGNOSIS

- No evidence of esophageal dilation, diverticulum formation, or stricture.
- Retention of mild amounts of contrast media in the oropharynx and laryngopharynx.

HOSPITAL NAME

Summit Dog & Cat
Hospital

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic presentation of the esophagus is within normal limits. No evidence of abnormal dilation, stricture, diverticulum, or deviation is seen.

REFERRING VET

Vogler

There is no evidence of aspiration pneumonia.

The mild residual contrast media within the pharynx may be due to swallowing/chewing during the exposure; however, oropharyngeal dysphagia, esophageal dysmotility, esophagitis, as well as laryngitis remain a potential.
