

PATIENT

Charlie Brumbly

PRESENTING CLINICAL SIGNS

NO CLINICAL SYMPTOMS. HIP DYSPLASIA CHECK

SPECIES

Canine

RADIOGRAPHIC STUDY OF THE PELVIS

Ventrodorsal hip extended view of the pelvis and mediolateral faux profile views of both femurs totaling 3 images available for review in jpeg format. There is no labeling on the ventrodorsal image. However, the lateralities in this report are established and reference to the positions of the descending colon and cecum.

BREED

German Shepherd

RADIOGRAPHIC FINDINGS

Moderate rightward tilting of the pelvis is seen which artificially creates the appearance of reduced femoral head coverage in the right coxofemoral joint. There is, however, no evidence of joint space incongruity, subluxation, or osteoarthritic changes.

SEX

Neutered Male

The left coxofemoral joint presents within normal limits. The femoral head is well covered by the acetabulum. The joint space is even and narrow. There is no evidence of subluxation or osteophytosis.

AGE

14 Months

RADIOGRAPHIC DIAGNOSIS

- No radiographic evidence of canine hip dysplasia.

INTERPRETED BY

Nele Eley, DVM
Dr. med. Vet. DipECVDI

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic presentation of both coxofemoral joints is within expected limits. The positioning benefits the left coxofemoral joint more so than the right joint. However, it is thought unlikely that the minor changes in the right coxofemoral joint are an expression of true hip laxity.
