PRESENTING CLINICAL SIGNS

History:

- Has 1cm soft dermal growth in popliteal area, and 1cm soft dermal growth on left side of rectum that both FNA as mast cell. Unknown duration, definitely chronic. Checking for metastasis.

COMPUTED TOMOGRAPHY OF THE THORAX & ABDOMEN

Pre/post contrast studies are provided for review.

COMPUTED TOMOGRAPHIC FINDINGS

Thorax

The lungs are regularly ventilated with close contact to the inner thoracic wall on all sides. There is no evidence of pleural thickening, fluid accumulation or free pleural gas. The pulmonary density is within normal limits; there is no evidence of focal or nodular pulmonary lesions. The mediastinum is regular in width and density. The mediastinal (sternal, tracheal-, bronchial) lymph nodes are considered to be normal.

The thoracic inlet presents subtly enlarged axillar lymph nodes.

The thoracic trachea and esophagus present as expected. The heart is inconspicuous as far as can be assessed with CT. The diaphragm appears normal.

The extra-thoracic soft tissues, the spine as well as the ribs and sternum are unremarkable. There is no evidence of an aggressive bone lesion and/or abnormal sclerosis.

Abdomen

Liver and spleen appear regular in terms of size, surface, shape and contrast behavior. Relevant focal or nodular lesions are not noted.

The gallbladder presents multiple calculi. The periphery and gallbladder wall are unremarkable.

The pancreas presents normal size and shape with a smooth surface. The peripancreatic fat tissue and omentum are inconspicuous.

Both kidneys and adrenal glands show marked calcifications within the recess and the renal pelvis, more prominent on the left than on the right side.

As far as can be assessed, the stomach and all parts of the intestine are inconspicuous without any indication of a wall thickening or a mass. There are no signs of an obstructive or functional ileus.

There is mild enlargement of the right medial inguinal and the celiac lymph node recognized.

Both ureters, the urinary bladder, trigone and urethra are presented as expected. There is no evidence of cystic calculi.

Signs of peritoneal/retroperitoneal effusion or free gas are not recognized.

The left perineal region presents a subcutaneous nodule of 1.6 cm with that density being well marginated.

COMPUTED TOMOGRAPHIC DIAGNOSIS

- Mild enlargement right medial inguinal, celiac and axillar lymph nodes

Incidental findings:

- Lipoma-like mass left perineal region 1,65 cm
- Severe and bilateral osteoarthritis stifles with bilateral medial patella luxation
- Bilateral, left pronounced nephrocalcinosis
- Cholelithiasis

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The mild enlargement of the lymph nodes is commonly seen with reactive lymphadenitis, which would be my favorite differential. However, this is an unspecific finding and not pathognomonic. For further differentiation, a follow-up study and/or sampling are needed. As far as can be assessed, there are no compelling signs of mediastinal or pulmonary metastases.

Especially liver and spleen present normal findings. This does not exclude diffuse infiltration concomitant with mast cell tumor. A complementary FNA and cytology could be performed next.

The left perineal nodule has fat density and likely presents a benign lipoma.
