PRESENTING CLINICAL SIGNS

Chronic RFL lameness. No responding to medical treatment. Radiographs performed in previous vets: NAD

COMPUTED TOMOGRAPHY OF THE ELBOWS & SHOULDERS

Plain study provided for review.

COMPUTED TOMOGRAPHIC FINDINGS

The displayed parts of the paws, metacarpal bones including the sesamoid bones and carpal joints are inconspicuous. There are no signs of a lytic/sclerotic process or soft tissue swelling. There is no evidence of a fracture or subluxation.

Both elbow joints look normal with well-defined bone surfaces and without signs of a fracture, sub-/luxation or an osteolytic/sclerotic process. The periarticular soft tissues are in expected normal limits. Especially the medial coronoid process is inconspicuous.

Both shoulder joints present a normal caudal humeral head. The bicipital groove is inconspicuous with a normal origin and course of the biceps tendon. The insertion of the infra- and supraspinatus muscles are unremarkable. There is no overt evidence of joint effusion. The periarticular soft tissues appear symmetrical.

COMPUTED TOMOGRAPHIC DIAGNOSIS

- Normal CT-findings forelimbs

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The CT findings do not explain the reported patient's history. Especially there are no asymmetric findings on the right side. Signs of relevant degenerative changes and/or a reactive inflammatory process are not noted. For further diagnostic, a complementary contrast study of the forelimbs, brachial plexus and the cervical spine could be performed next.

The information and recommendations provided are based on the images presented by the referring veterinarian/sonographer. No evaluation can be communicated regarding pathology that was not visible in the image/video clips provided.

Thank you for this referral. If the clinical or image interpretation does not parallel your findings or if I can be of any further assistance, please contact me.
