

PATIENT PRESENTING CLINICAL SIGNS

Jasmine Steele History: RH lameness. Suspect CCL injury
Abnormal PE/Chem/CBC/UA Results: N/A

SPECIES ULTRASONOGRAPHIC EXAMINATION OF THE RIGHT STIFLE

Canine There is no joint effusion noted.

BREED The intraarticular fat body appears mildly inhomogeneous and irregular. Cystic changes are missing.
Coton de Tulear The cranial cruciate ligament shows a hyperechoic stump with a mild peripheral halo. Some loops present a broad and intact ligament.

ULTRASONOGRAPHIC DIAGNOSIS

SEX • Suspected partial rupture of the CCL

Spayed Female

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

AGE The sonographic findings show a lesion of the CCL that most likely represents a partial tear of the ligament. The hyperechoic stump and the surrounding halo would go along with that assumption. A relevant joint effusion is not recognized, a complete rupture therefore seems unlikely. Sonographic findings must be correlated with the clinical presentation (instability, cranial drawer, pain, acute vs. chronic).
