PRESENTING CLINICAL SIGNS

Woke up morning of 1.3.26 and would not bear weight on LF leg. Owner got her about 3 weeks ago. Has had intermittent limping most likely on LF leg. Owner did not see her injure herself.

RADIOGRAPHIC STUDY OF THE LEFT ELBOW JOINT

Radiographs of the left elbow joint in two orthogonal image planes are provided for review.

RADIOGRAPHIC FINDINGS

The growth plates are age related visible.

The osseous and surrounding soft tissue structures of the left elbow joint are within normal limits.

RADIOGRAPHIC DIAGNOSIS

- Normal left elbow joint

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study of the left elbow joint reveals no abnormalities. Anyway, due to the young age, signs of elbow dysplasia can be missed. The subchondral bone at the caudal aspect of the left humeral head is mildly flattened and irregular that can be due to normal growth or be indicative for an OCD lesion. Recommend follow up radiographs of the elbow joint and left shoulder joint once the patient is over six months of age; a CT study can be considered alternatively.
