

PATIENT PRESENTING CLINICAL SIGNS

Storm McCormark History: Chronic intermittent lameness of right hind limb , cbc chem normal, 4dx negative
Abnormal PE/Chem/CBC/UA Results:

SPECIES RADIOGRAPHIC STUDY OF THE PELVIS AND STIFLE JOINTS

Canine Radiographs of the pelvis in a VD projection and the stifle joints in two orthogonal imaging planes are provided for review.

BREED RADIOGRAPHIC FINDINGS

Husky Mix The osseous and surrounding soft tissue structures of the pelvis are within normal limits. The coxofemoral joints present smooth margins with congruent joint spaces.

SEX The periarticular boones of the right stifle joint present mild osteophyte new bone formation. The osseous margins of the left stifle joint are smooth. Both stifle joints present a mild to moderate, R>L, intracapsular soft tissue swelling, effacing the infrapatellar fat pad cranially and distorting the fascial plane caudally.

Spayed Female

AGE RADIOGRAPHIC DIAGNOSIS

- Very mild degenerative osteoarthritis right stifle joint
- Articular swelling stifle joints bilaterally

2 Years

INTERPRETED BY INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

Sebastian Schaub, DVM Dr. med. vet. DipECVDI The radiographic study is consistent with right sided mild degenerative osteoarthritis of the right stifle joint and mild joint effusion of both stifle joints. Although the most-likely underlying cause is (partial) rupture of the cranial cruciate ligament with or without meniscal disease., due to the bilaterally present joint effusion, a synovial tap can be used to rule out underlying arthritis (e.g. polyarthritis). Check if there is a positive drawer sign or tibial compression test under general anesthesia.
