PRESENTING CLINICAL SIGNS

Patient painful at home per client, though unsure where. On physical exam, patient seemed uncomfortable with palpation of lumbo-sacral region. Stifles are thick with palpation, though no swelling appreciated. Ambulatory x4 with no lameness appreciated. Patient able to jump up on bench without pain.

Abnormal PE/Chem/CBC/UA Results: cbc/chem unremarkable.

RADIOGRAPHIC STUDY OF THE STIFLE JOINTS

Radiographs of the abdomen including the stifle joints are provided for review.

RADIOGRAPHIC FINDINGS

In the lateral projection, both stifle joints are superimposing on each other.

The periarticular bones of both stifle joints present mild to moderate osteophyte new bone formation. There are multiple mineralized, well-defined, roundish mineralized bodies seen along the caudal aspect of both stifle joints – level with the joint capsule.

RADIOGRAPHIC DIAGNOSIS

- Degenerative osteoarthritis stifle joints bilaterally
- Periarticular mineralization stifle joints bilaterally

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study presents evidence of degenerative joint disease of both stifle joints, acute on chronic insult may have caused the acute onset of clinical signs. The periarticular mineralization of both stifle joints is most consistent with synovial osteochondromatosis/metaplasia of the joint capsule and considered as an incidental finding that is commonly not associated with clinical signs.

Check clinically if a positive drawer sign or tibial compression test is present to rule out pathology of the cranial cruciate ligament.
