PRESENTING CLINICAL SIGNS

History: Intermittent front leg lameness, responds to steroids but then returns off of it O says that after the pred was finished that P started to limp again and favor L front leg. O did give 1 dose of Rimadyl yesterday. no other concerns at this time No current Medications

COMPUTED TOMOGRAPHIC STUDY OF THE NECK AND SHOULDER JOINTS

A high resolution pre- and post-contrast CT study of the neck and shoulder joints is provided for review.

COMPUTED TOMOGRAPHIC FINDINGS

Both temporomandibular joints present congruent joint spaces with even subchondral bone surfaces and are considered within normal limits.

Both tympanic bullae are aerated, the mucosal lining is not seen, the bony wall is smooth and thin. The external ear canals are within normal limits.

The submandibular and medial retropharyngeal lymph nodes are small and elongated with a normal short-to-long-axis-ratio is < 0.5, the attenuation and contrast enhancement pattern is uniform.

The osseous and soft tissue structures of the cervical spine are within normal limits.

The distal aspect of the bicipital groove of the right humerus presents mild to moderate exostosis formation. The remainder of the osseous structures of the right shoulder joint present smooth margins. The osseous and surrounding soft tissue structures of the left shoulder joint are unremarkable.

COMPUTED TOMOGRAPHIC DIAGNOSIS

- Mild exostosis formation bicipital groove right humerus
- Normal neck/cervical spine
- Normal left shoulder joint

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The mild exostosis formation in the bicipital groove of the right humerus is likely an incidental finding but can be indicative for underlying pathology of the bicipital tendon.

Check the elbow joints as they present signs of degenerative joint disease due to elbow dysplasia as likely cause for the presenting clinical signs.
