

**PATIENT**

Billy Blaski

PRESENTING CLINICAL SIGNS

Billy presented for recheck for right hind limb lameness. He had been bitten by another animal and the wounds appeared to have completely healed but he remained lame. Previous radiographs did not show evidence of bone involvement in the hock. A small amount of synovial effusion was noted.

SPECIES

Feline

COMPUTED TOMOGRAPHY OF THE HIND LIMBS

A high resolution plain CT study of the hind limbs is provided for review.

BREED

DSH

COMPUTED TOMOGRAPHIC FINDINGS

The stifle joints are not included within the field of view.

The osseous and surrounding soft tissue structures of the pelvis are within normal limits. Both coxofemoral joints present smooth osseous margins and congruent joint spaces.

SEX

MN

The volume of the right thigh musculature is decreased in comparison to the left thigh musculature.

AGE

3 Years

The right tibiotarsal joint presents a moderate intracapsular soft tissue swelling. Mild immature periosteal new bone formation is seen along the caudal aspect of the distal segment of the tibia.

COMPUTED TOMOGRAPHIC DIAGNOSIS

- Moderate articular swelling right tibiotarsal joint
- Mild immature periosteal new bone formation caudal aspect distal segment left tibia
- Disuse atrophy musculature left hind limb
- Normal pelvis

INTERPRETED BY

Sebastian Schaub, DVM

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The articular swelling of the right tibiotarsal joint and mild immature periosteal new bone formation along the distal aspect of the right tibia are concerning for arthritis – in combination with the history of bite wound, septic arthritis is a consideration. If not done so yet, complementing workup by a synovial tap is mandatory for further definition. If there are signs for instability of the right tarsal joint, recommend stressed radiographs.
