

PATIENT PRESENTING CLINICAL SIGNS

Oliver Miyairi History: limping and non-weight bearing on R hind limb
Abnormal PE/Chem/CBC/UA Results: patellar instability R hind leg

SPECIES RADIOGRAPHIC STUDY OF THE STIFLE

Canine Radiographs of the stifle joints in two orthogonal imaging planes are provided for review.

RADIOGRAPHIC FINDINGS

BREED

Yorkshire Terrier X

The volume of the right thigh musculature is mildly decreased.

Mild osteophyte new bone formation is seen at the proximal aspect of the femoral trochlear ridge of the right stifle joint. The right stifle joint presents a mild intracapsular soft tissue swelling in comparison to the contralateral side.

SEX

Neutered Male

The osseous and surrounding soft tissue structures of the left stifle joint present no abnormalities. The patella bilaterally is in situ.

AGE

7 Years

RADIOGRAPHIC DIAGNOSIS

- Mild degenerative osteoarthritis right stifle joint
- Mild articular swelling right stifle joint
- Disuse atrophy right thigh musculature
- Normal left stifle joint

INTERPRETED BY

Sebastian Schaub,
DVM Dr. med. vet.
DipECVDI

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study is consistent with mild degenerative osteoarthritis with concomitant joint effusion of the right stifle joint. Due to the age of the patient the clinical relevance of the patellar luxation is unclear and underlying (partial) rupture of the cranial cruciate ligament with or without meniscal disease needs to be ruled out.

HOSPITAL NAME

Truscott AH

A positive drawer sign or tibial compression test under general anesthesia would be beneficial to confirm the diagnosis.
