Gradually losing weight, eating and drinking okay, urinating okay, has had watery diarrhea for the past 2-3 weeks. Weight went from 20.6 kg in November of 2022 - down to now 18.20 in February 2023. Has been also coming in for labored breathing for a few months now. Was diagnosed with inflammatory bowel disease in September, 2022. Meatball is also anemic. If there are ANY abnormalities in these radiographs, please let us know. Meatball is a cherished fellow here. Abnormal PE/Chem/CBC/UA Results: Attached the comprehensive bloodwork results from IDEXX. Attached the radiographs as well.

RADIOGRAPHIC STUDY OF THE ABDOMEN

Radiographs of the abdomen in three imaging planes are provided for review. Radiographs are provided in JPEG file format.

RADIOGRAPHIC FINDINGS

The vertebral endplates L6/L7 and L7/S1 present mild spondylosis formation. Proximal to the greater trochanter of the left femur, a well-defined, roundish mineral opaque body is seen.

No abnormalities of the extraabdominal soft tissues are noted. The abdominal wall is smooth and thin.

The serosal detail is decreased due to lack of peritoneal fat.

The liver is appropriate in position, size and presents uniform opacity.

The splenic head is in the anticipated position and within normal limits for size and opacity.

The kidneys cannot be delineated. The urinary bladder is in its anticipated position. No radiopaque calculi are noted throughout the upper and lower urinary tract.

The stomach is in its anticipated position and contains a mild to moderate amount of gas.

The small intestinal loops are of even diameter and generalized mild to moderately dilated by gas.

The colon is seen in the expected position and presents with appropriate content.

RADIOGRAPHIC DIAGNOSIS

- Decreased serosal abdominal detail
- Gas pattern gastrointestinal tract
- Metaplasia proximal to greater trochanter left femur
- Spondylosis deformans caudal lumbar spine

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The radiographic study of the abdomen presents without abnormalities, explaining the weight loss. The generalized decreased serosal detail is considered as a sequela to decreased volume of peritoneal fat. Complementing workup by an abdominal ultrasound examination would be ideal for further assessment of the abdominal organs.
