

PATIENT PRESENTING CLINICAL SIGNS

Henry Popovic Recently removed low grade sarcoma from Left side of chest; no hx of weight loss, doing well; long hx of intermittent cough.

SPECIES RADIOGRAPHIC STUDY OF THE THORAX

Canine Radiographs of the thorax in three imaging planes are provided for review.

RADIOGRAPHIC FINDINGS

BREED Mild spondylosis formation is seen along the mid segment of the thoracic spine.

Airedale The extrathoracic soft tissues present homogeneous without abnormalities.

SEX The heart is of normal size and shape, there is no evidence of cardiac chamber or vascular enlargement. The pulmonary vasculature is within normal limits.

Male The cranial mediastinum presents the expected soft tissue opacity. The mediastinal width is less than twice the width of the vertebral column at the same level.

AGE The trachea is normal in diameter and presents the anticipated course. The luminal outline of the trachea is smooth.

11

INTERPRETED BY The bronchial tree presents with thin walls and tapers uniformly towards the periphery as expected.

Sebastian Schaub, DVM Dr. med. vet. DipECVDI The lung parenchyma presents the expected architecture and generalized ground glass opacification; the intrapulmonary vascular branching is seen up to the third order lung vessels.

HOSPITAL NAME The diaphragm is well delineated with even surface and the expected mild cranial bulging of the diaphragmatic cupola.

Stuga North Veterinary Care

RADIOGRAPHIC DIAGNOSIS

- Unstructured interstitial lung pattern
- Spondylosis deformans
- No signs for pulmonary metastatic disease

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

INVOICE The unstructured interstitial lung pattern is likely a sequela to the age related changes of the lung parenchyma. The odds for 'real' interstitial lung pattern are considered low, potentials would include fibrosis, pneumonitis (inflammatory versus infectious), systemic disease (e.g. pancreatitis, IMHA, renal disease), neoplasia.
