**DATE**

5-6-22

## PRESENTING CLINICAL SIGNS

Owner reports intermittent lameness on left hind leg, particularly following activity. On exam, pet exhibited mild resistance to extension of left hip.
Abnormal PE/Chem/CBC/UA Results: 4DX: Negative x 4

## RADIOGRAPHIC STUDY OF THE PELVIS

A ventrodorsal view of the pelvis is provided for review.

## RADIOGRAPHIC FINDINGS

The acetabular groove bilaterally is shallow, and the center of the femoral heads is lateral to the dorsal acetabular rim. The joint space of the coxofemoral joints bilaterally is incongruent and widened medially. Mild osteophyte formation is seen at the proximal aspect of the femoral neck bilaterally.

## RADIOGRAPHIC DIAGNOSIS

- Hip dysplasia with mild degenerative osteoarthrosis of the coxofemoral joints

## INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

The findings are consistent with hip dysplasia with possible increased laxity of the coxofemoral joints and early stage of degenerative joint disease. If pain can be allocated to the coxofemoral joints, consider discussing conservative therapeutic options – such as professional physical therapy and pain management if indicated – versus surgical options with orthopedic specialist.
