RADIOGRAPHIC STUDY OF THE THORACIC & LUMBAR SPINE

Radiographs of the thoracic and lumbar spine are provided for review.

BREED

Tibetan Terrier

RADIOGRAPHIC FINDINGS

The intervertebral disc space T6/T7 and T12/T13 are narrowed. The remainder of the osseous and soft tissue structures of the thoracic spine are within normal limits.

SEX

Male Neutered

The intervertebral disc space L1/L2 is collapsed and the respective vertebral endplates present moderate spondylosis formation. Level with the intervertebral disc space L1/L2, mineral opaque material is superimposed on the respective neuroforamina, occupying approximately 40% of the height of the vertebral canal at the same level. The remainder of the osseous and soft tissue structures of the lumbar spine are unremarkable.

AGE

11 Years, 6 Months

RADIOGRAPHIC DIAGNOSIS

- Discopathy L1/L2 with potential herniation of mineralized disc material into the vertebral canal
- Discopathy T6/T7 and T12/T13
- Spondylosis deformans L1/L2

INTERPRETED BY

Sebastian Schaub, DVM
Dr. med. vet. DipECVDI

INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS

HOSPITAL NAME

DTLAvets

The mineralized material superimposed on the neuroforamina L1/L2 is highly suggestive for herniation of mineralized disc material into the vertebral canal ± compressive myelopathy.

The narrowed intervertebral disc spaces also indicate discopathy that may or may not be associated with compressive myelopathy.

REFERRING VET

Dr. Montoya

Depending on the neurological status, workup might be complemented by cross-sectional imaging of the spine.
