

**PATIENT PRESENTING CLINICAL SIGNS**

Marty Silvano History: lameness - able to apply 75% weight rh - responsive with nsaid therapy  
Abnormal PE/Chem/CBC/UA Results: wnl

**SPECIES RADIOGRAPHIC STUDY OF THE RIGHT STIFLE JOINT**

Canine Radiographs of the right stifle joint are provided for review.

**RADIOGRAPHIC FINDINGS**

**BREED**

Havanese The volume of the musculature of the right thigh is mildly decreased in comparison to the left hind limb.

**SEX**

Neutered Male

The periarticular bones of the right stifle joints present moderate osteophyte new bone formation. The patella of both stifle joints is superimposed on the medial femoral condyle in the craniocaudal projection. Moderate cranial subluxation of the right tibia is appreciated. The right stifle joint presents a moderate intracapsular soft tissue swelling.

**AGE**

6 Years

**RADIOGRAPHIC DIAGNOSIS**

- Degenerative osteoarthritis right stifle joint
- Moderate articular swelling right stifle joint
- Right cranial tibial subluxation
- Medial patellar luxation bilaterally

**INTERPRETED BY**

Sebastian Schaub,  
DVM Dr. med. vet.  
DipECVDI

**INTERPRETATION OF THE FINDINGS & FURTHER RECOMMENDATIONS**

The cranial subluxation of the right tibia is suggestive for failure of the cranial cruciate ligament and secondary degenerative osteoarthritis – the latter might be accentuated by the medial patellar luxation. Due to the age of the patient, the medial patellar luxation can be an incidental finding not related with the acute presenting clinical signs. A positive drawer sign or tibial compression test under general anesthesia will support the diagnosis – partial rupture of the cranial cruciate ligament and potential thickening of the synovial capsule can result in only mild instability.
